LANDSLIDE AREAS IN MORTON COUNTY

Landslides are masses of rocks and soil that haveumbled or slid down a slope under their own weight. These phenomena are common in the state of North Dakota. In the Western Slope area, landslides occur in the mined land areas of the western part of the county. These landslides are generally characterized by the following features: (1) steeper slopes where the soil and rock have been eroded by downward movement; (2) a layer of soil and rock that has been moved downslope; and (3) a visible effect on the landscape.

Landslides are readily observed in the mining areas of the Western Slope, where the mined land areas are generally characterized by steep slopes, a layer of soil and rock that has been eroded by downward movement, and a visible effect on the landscape.
